Digestive System

rectum	Faeces is egested here.
large intestine	Faeces is stored here.
small intestine	Water absorption and faeces production happen here.
mouth	Contains villi to help absorption into the bloodstream.
stomach	The start of the digestive system - both mechanical and chemical changes happen here.
anus	Very small blood vessel found in villi.
capillary	Chemicals that break down food in the digestive process.
enzymes	These speed up the rate of reaction and remain unchanged.

twinkl.com

carbohydrate	Also called fats - these are needed for energy and insulation.

saliva	Long tube that runs from the mouth to the stomach.

protein	This is needed in the diet for roughage and to help you egest faeces.

catalysts	Contained in the mouth and aids digestion.

lipids	This is needed for growth and repair and is found in meat, eggs and fish.

oesophagus (gullet)	This is needed for energy and can be found in bread, pasta and potatoes.

fibre	Essential to all body processes and to life itself.

water	This enzyme breaks down starch into simple sugars.

twinkl.com

bile	This enzyme breaks down carbohydrates.

digestion	The process of passing out the waste, undigested food as faeces.

teeth	The process of breaking down large food molecules into smaller ones.

lipase	This enzyme breaks down proteins.

egestion	This enzyme breaks down lipids (fats and oils).

amylase	This is produced in the liver and emulsifies fats to aid digestion.

protease	Found in the small intestine, these increase surface area and help absorption.

carbohydrase	These help break your food down into smaller pieces to make it easier to swallow.

twinkl.com

liver	This organ stores bile.

soluble	If something doesn't dissolve in a solvent it is...

excretion	Single celled microorganisms.

appendix	This organ produces enzymes to help digestion.

villi	If something dissolves in a solvent it is...

pancreas	This organ produces bile.

insoluble	This organ is no longer needed for digestion and can be removed if it becomes infected.

gall bladder	Waste products from chemical reactions are removed using this process.

circulatory system	Strong acid is here to help digestion and kill bacteria.

digestive system	Glucose from the digestive system goes into this to get around the body.

starch	Food goes through this and is broken down and absorbed.

bacteria	This is used to model the digestive system.

visking tubing	Broken down into glucose during digestion.

Digestive System **Answers**

mouth	The start of the digestive system, both mechanical and chemical happen here
small Intestine	Contains villi to help absorption into the blood stream
large Intestine	Water absorption and faeces production happens here
rectum	Faeces is stored here
anus	Faeces is egested here
capillary	Very small blood vessel found in villi
enzymes	Chemicals that break down food in the digestive process
catalysts	These speed up the rate of reaction and remain unchanged
saliva	Contained in the mouth and aids digestion
oesophagus (gullet)	Long tube that runs from the mouth to the stomach
carbohydrate	This is needed for energy and can be found in bread, pasta and potatoes
lipid	Also called fats, these are needed for energy and insulation
protein	This is needed for growth and repair and is found in meat, eggs and fish
fibre	This is needed in the diet for roughage and to help you egest faeces
water	Very important to all body processes and to life itself
amylase	This enzyme breaks down starch into simple sugars
bile	This is produced in the liver and emulsifies fats to aid digestion
carbohydrase	This enzyme breaks down carbohydrates
catalyst	This changes the rate of reaction
digestion	The process of breaking down large food molecules into smaller ones
egestion	The process of passing out waste, undigested food as faeces
lipase	This enzyme breaks down lipids (fats and oils)
protease	This enzyme breaks down proteins

villi	Found on the small intestine, these increase surface area and help absorption
soluble	If something dissolves in a solvent it is...
Insoluble	If something doesn't dissolve in a solvent it is...
appendix	This organ is no longer needed for digestion and can be removed if it becomes infected
pancreas	This organ produces enzymes to help digestion
liver	This organ produces bile
gall bladder	This organ stores bile
excretion	Waste products from chemical reactions are removed using this process
bacteria	Single celled micro-organisms
Visking tubing	This is used to model the digestive system
starch	Broken down into glucose during digestion
digestive system	Food goes through this and is broken down and absorbed
circulatory system	Glucose from the digestive system goes into this to get around the body
stomach	Strong acid is here to help digestion and kill bacteria
