Waste systems

As well as bringing good things to the cells, the circulatory system also takes away bad things. After cells have used up the energy that they release from glucose, certain waste products are left behind. These can become poisonous if they remain in the cells and build up. So the cells release these waste products.

Blood cells take the waste products away to other organs that are designed to deal with waste safely. The kidneys, liver, lungs and skin are some of the organs involved in waste removal.

☞ **1** Write these phrases in the correct places in the table.

- get their energy from glucose
- and deliver waste products to the organs to be dealt with safely
- and takes away bad things from the cells

The bloodstream	brings good things to the cells	
Cells		and release waste products from glucose.
Blood cells	take nutrients to the cells that make up the organs	

2 Using your own knowledge, match these waste products with the organs that help remove them from the body.

Waste products	**Forms**	**Organs**
salts and water	urine and sweat	**a)** **b)**
carbon dioxide and water vapour	as gas that is breathed out	**c)**
