Body systems

The bodies of animals and humans have billions of cells that are organised into tissues and organs. Groups of organs make up **body systems**. These systems help animals and humans stay healthy and active.

The body systems in an organism are **interdependent**. This means that each of the systems relies on the other systems. For example, the respiratory system supplies the human body with oxygen, and the circulatory system transports this oxygen around the body to the cells.

☞ **1** Draw a line between the name of each of these human body systems and its description.

a)	central nervous system	the system that removes waste products from the body
b)	circulatory system	the system of bones, cartilage, ligaments and tendons
c)	digestive system	the system that includes the sex organs
d)	reproductive system	the system that passes electrical signals to and from the brain
e)	respiratory system	the system that transports blood around the body
f)	excretory system	the system that deals with the taking in and processing of food
g)	skeletal system	the system that includes the organs used for breathing, or respiration

2 **a)** In your own words, write a definition for *interdependence*.

b) Write down two body systems from Question 1 that you think are interdependent. Explain why.
