Plant structures

Most green plants have some common structures. These structures play different parts in the process of making food (photosynthesis) and distributing this food around the plant.

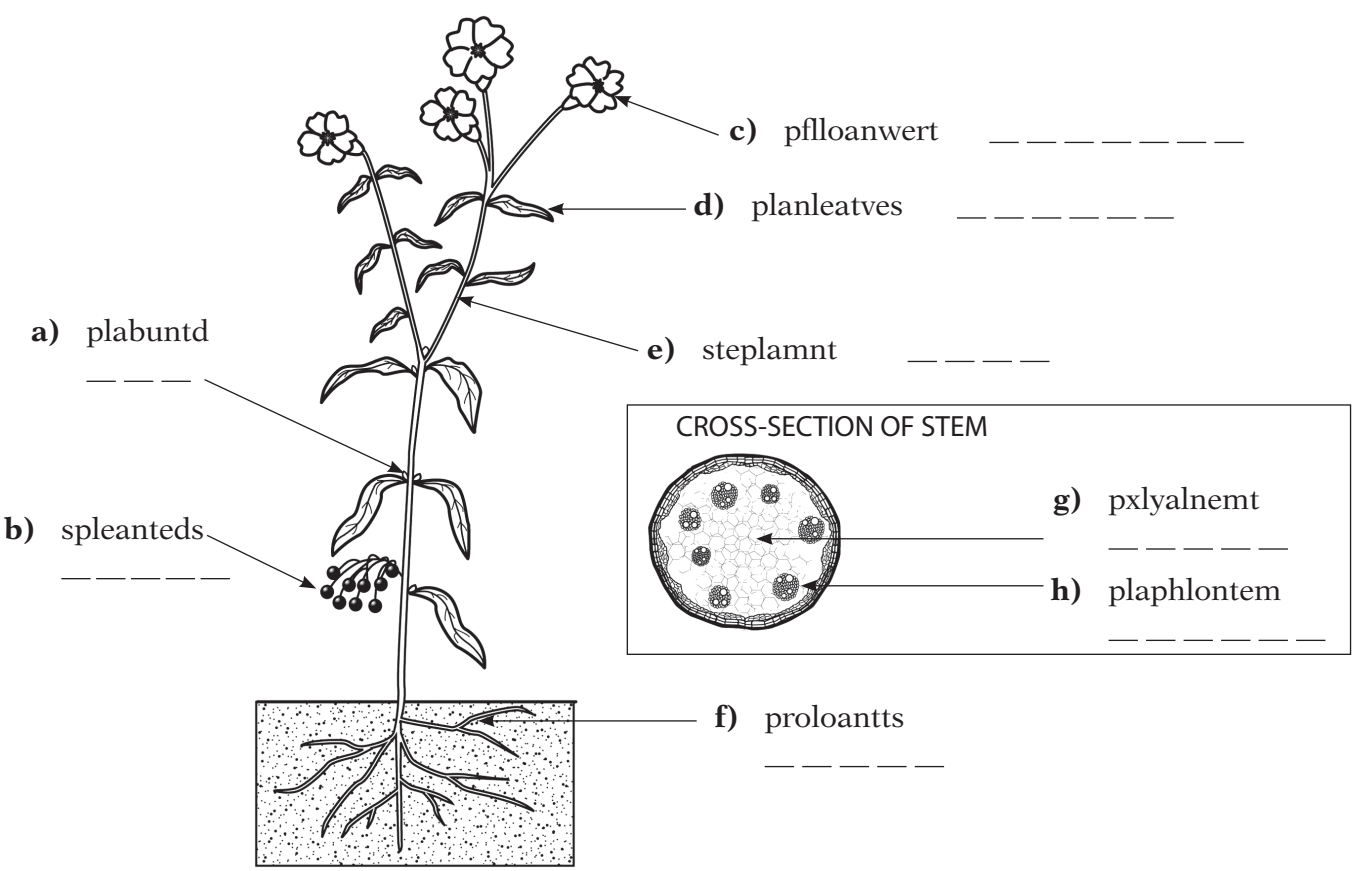

In most flowering plants, there are roots below the ground. They keep the plant in place by holding on to the soil. Roots absorb water for the plant to use in photosynthesis.

Cells in the plant's leaves carry out the work of photosynthesis, creating food (glucose) by absorbing sunlight and using water and carbon dioxide.

Many flowering plants have a system of tubes inside their stems. Two of these tubes are called the xylem and the phloem.

- The **xylem** carries water from the plant's roots around to all the plant's cells.
- The **phloem** carries food (glucose) from the leaves to the rest of the plant. This gives each cell the energy it needs to survive and grow.

☞ **1** Extra letters have been added to these eight words, which label the parts of the plant. In each case, the extra letters spell *p l a n t*. Cross out the letters p, l, a, n and t from each word puzzle in order.
