Divide the cell below and group the correct statements into the two cells beneath.

Produces gametes.

Involved in asexual reproduction.

In humans, daughter cells have 23 chromosomes.

Daughter cells are haploid.

Four daughter cells are formed from original cell.

Daughter cells are diploid.

Occurs in testes and ovaries.

Daughter cells have homologous pairs of chromosomes.

One cell forms two daughter cells.

Causes growth.

Meiosis

Mitosis

Q) Which type of cell division, if any, is this activity is analogous to and why?

.....

.....

.....

.....

Teaching notes

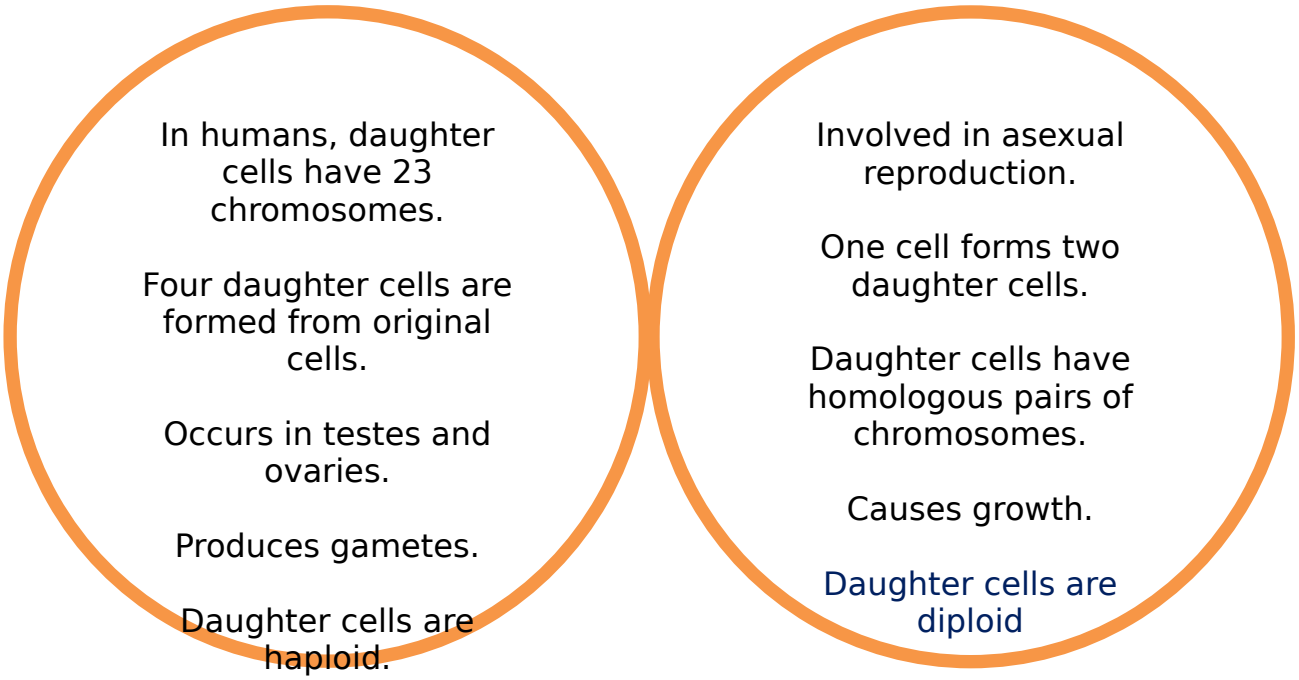
This is a quick starter or plenary.

Students must move the statements from the central ‘cell’ and place them in the appropriate ‘daughter cell’.

There should be an equal number of statements in each ‘daughter cell.’

At the end, you could ask students to decide which type of cell division, if any, this activity is analogous to and why.

Answers



Q) Each daughter cell has half the amount of information as the parent cell, which suggests
meiosis, but only two daughter cells are produced, suggesting mitosis!
