Gas Exchange

This happens in the alveolus in the lungs.

Oxygen (O_2) in the alveolus is exchanged for Carbon dioxide (CO_2) in the blood.

Air which has been inhaled has a higher concentration of Oxygen and a lower concentration of Carbon Dioxide.

Blood which has travelled around the body has a higher concentration of Carbon Dioxide and a lower concentration of Oxygen.

These gasses are exchanged in the alveolus via diffusion.

So the blood leaving the lungs is now higher in Oxygen and the air which is exhaled from the lungs is higher in Carbon dioxide.
