1. Working with a partner match the part of a microscope to its definition.
2. Cut out the label and definition and place them in your exercise book. DO NOT GLUE IN.
3. When you are sure that the definitions are correct, glue them into your exercise book
4. Put scrap paper into the class recycling bin.

Eyepiece Lens	Usually you will find 3 or 4 of these on a microscope. They almost always consist of 4X, 10X, 40X and 100X powers. When coupled with a 10X (most common) eyepiece lens, we get total magnifications of 40X (4X times 10X), 100X , 400X and 1000X
Tube	The flat platform where you place your slides
Arm	Small, round knob on the side of the microscope used to fine-tune the focus of your specimen after using the coarse adjustment knob.
Base	The lens at the top that you look through. They are usually 10X or 15X power.
Mirror	Connects the eyepiece to the objective lenses
Stage	Large, round knob on the side of the microscope used for focusing the specimen; it may move either the stage or the upper part of the microscope.
Stage clips	A rotating disk under the stage. It has different sized holes and is used to vary the intensity of light that is projected upward into the slide.
Revolving Nosepiece	Supports the tube and connects it to the base
Objective Lenses	Used to reflect light from an external light source up through the bottom of the stage.
Diaphragm (or Iris)	The bottom of the microscope, used for support
Coarse adjustment knob	This is the part that holds two or more objective lenses and can be rotated to easily change power.
Fine adjustment knob	Hold the slides in place. If your microscope has a mechanical stage, you will be able to move the slide around by turning two knobs. One moves it left and right, the other moves it up and down.
