The Structure of Cells (p48-50)

Cells are like little chemical factories, constantly making new substances and breaking down others.

Your skin, muscles, blood and brain are all made up of different types of cells. Some cells are very simple, such as bacteria, and some are more complex, like a hen's egg.

Parts of Cells

Every cell performs basic functions and has four main parts, or structures, that can be seen clearly using a light microscope. These parts are the cell membrane, the nucleus, the cytoplasm and the vacuole. Write the functions of each structure in the spaces below.

Cell membrane:_____

_____

_____

Nucleus:

_____

_____

_____

Cytoplasm:

_____

_____

_____

Vacuole:

_____

_____

_____

The cytoplasm contains many smaller structures that carry out special functions. These parts are called **organelles** (organs of the cell). The functions of the following cell parts are:

Mitochondria:

_____

_____

Ribosomes:

_____

_____

Lysomes:

_____

_____

Endoplasmic reticulum:

_____

_____

Plants contain some parts that are not found in animal cells. These are cell walls and chloroplasts. The functions of these parts are:

Cell wall:

_____

_____

Chloroplast:

_____

_____

Briefly explain the process of photosynthesis.

Fungal cells have similarities and difference with both plant and animal cells.

How are fungal cells similar to animal cells?

How are fungal cells similar to plant cells?

How are fungal cells different to plant cells?

In the space below, draw and label the three types of cells.

Animal Cell **Plant Cell**

Fungal Cell
