

Cell structure - an overview

Cells are composed of many different organelles that serve separate purposes within the cell.

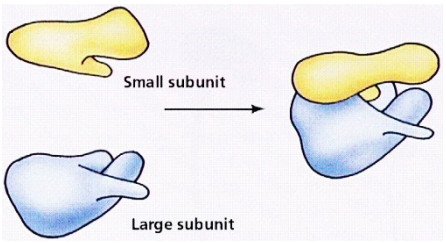

The Cell Membrane separates the _____ of the cell from it's _____.

The Cytosol or Cytoplasm is a _____ found in the cell. The organelles are suspended in the cytosol.

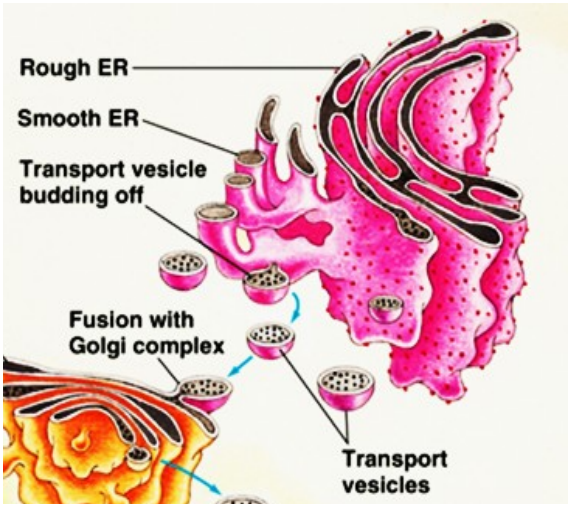

The Nucleus is the _____. The nucleus _____ or _____. DNA dictates _____ and how it is going to do it (through controlling the productionof proteins).

The Nucleolus is a structure where _____ are made.

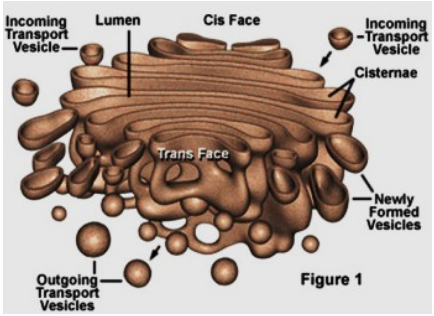

Ribosomes make _____ from amino _____.

Smooth Endoplasmic Reticulum is where the transport nutrients and _____.

Rough Endoplasmic Reticulum has _____ attached to it.

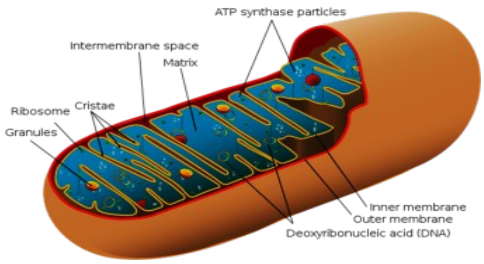

The Golgi Apparatus sometimes called the _____ _____. It is responsible for the _____ of proteins and the _____ of lipids and _____ to them.

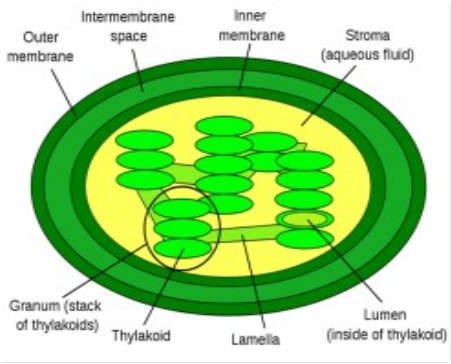

The Vacuole are _____ _____ that store _____. *Vacuoles are especially important in plant cells as they provide internal support to cell rigidity. When a vacuole shrinks through water loss you can see the leaves of the plant wilt.*

Lysosomes are the _____ _____. They take in _____ or _____ cell parts. Lysomes contain _____ which breakdown this _____.

Mitochondria are the _____ of the cell. During _____ the mitochondria make ATP molecules which provide all the _____ the cell needs. Cells which need more _____ have more _____.

The **Cytoskeleton** holds the threadlike _____ and _____ which help hold the cell together.

Chloroplasts is where _____ occurs. This is where carbon dioxide and water are converted to glusose and oxygen. Chloroplasts are green because they contain _____.

A **cell wall** is in plant cells. A cell wall is outside the cell _____ and it shapes, _____, and _____ the plant cell. It is made of cellulose, a tough protein.
