# Gills vs lungs

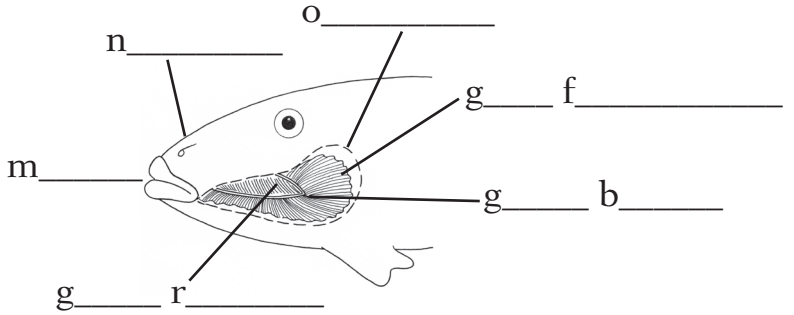

Fish and humans both need **oxygen** to breathe. Humans inhale air, which travels through the trachea into the lungs. Each lung is filled with tiny air sacs called alveoli, which transfer oxygen from the air into our **bloodstream**. This is exchanged for **carbon dioxide** which is **expired** when we breathe out. Fish take oxygen from the water when they open their mouths. Oxygen diffuses from the water into the gills and then enters the bloodstream.

☞ **1** Use the word lists to label the diagrams.

human lungs

| |
|---|
| trachea |
| bronchus |
| bronchiole |
| mouth |
| nostril |
| air sacs |

fish gills

| |
|---|
| gill rakers |
| gill bar |
| gill filaments |
| mouth |
| nostril |
| operculum |

**2** Label these statements true or false.

**a)** Water pumps over the gills when a fish opens and shuts its jaws. _____

**b)** Humans do not have gills. _____

**c)** Expiration is when air enters through the mouth. _____

**d)** Human lungs have many air passages that end in alveoli. _____

**e)** Fish can suffocate on land. _____

**f)** Oxygen diffuses from the gill filaments into the water. _____

**3** Rewrite the false sentences to make them correct.

_____

_____
