Meiosis vs mitosis

☞ **1** Circle the correct word in each pair.

Mitosis is when a nuecleus/nucleus divides and pairs of **chromosomes** are reproduced. Each **daughter cell** has the same number of chromosomes/cromosomes as the **parent cell**. This is called the **diploid** number/numbre of chromosomes. Mitosis takes place in sells/cells throughout the body or plant wherever growth occurs. Once an organist/organism has reached maturity mitosis/mytosis is rare, except where cells are being replaced.

Meiosis happens in the reproductive organs/oargans of sexually reproducing/reproduce organisms. Meiosis is when a nucleus divides/divide and pairs of chromosomes are separated, forming two new cells. Each new cell is called a **gamete**. Grametes/gametes each have halve/half the number of chromosomes as the parente/parent cell. This is called/cold the **haploid** number of chromosomes.

Fertilisation occurs/ocurs when the gamete from the mail/male fuses with the gamete from the female. The combined/combine gametes each contribute their harploid/haploid number of chromosomes, creating/creates an individual with a diploid number of chromosomes.

2 Fill out the tables below.

	Mitosis
Where it occurs in plants	
Where it occurs in animals	
Number of chromosomes compared to parent cell	

	Meiosis
Where it occurs in plants	
Where it occurs in animals	
Number of chromosomes compared to parent cell
