Vaccinations

Vaccines are liquids that contain either dead **germ** particles or harmless live germs. The germs used to make a vaccine are similar to the germs that cause the **disease** being vaccinated against. When a vaccine enters the bloodstream, the body reacts as if it were actually suffering from an infection and makes **antibodies**. The antibodies stay in the blood for a long time, making the body **immune** to a real infection.

Scientists have produced vaccines for a range of deadly diseases such as tetanus, diphtheria and measles. Most vaccinations are injected but some, such as the polio vaccine, are swallowed.

☞ **1** If vaccines contain germ particles why doesn't the vaccinated person become sick with the disease? _____

_____

_____

2 Another word for immune is:

a) susceptible **b)** reluctant **c)** vulnerable **d)** resistant

3 How are vaccines given to humans? _____

4 List as many other kinds of vaccinations as you can think of.

_____

_____

5 Match the phrases below.

Before vaccinations, smallpox	are taken orally.
Smallpox was a	occurred in Somalia in 1977.
Vaccines have been	killed thousands of people every year.
Some vaccinations	against serious diseases.
Even pets are vaccinated	highly infectious disease.
The last case of smallpox	developed for many diseases.
