Selective breeding

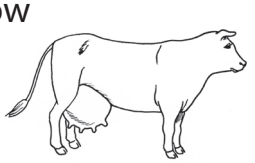

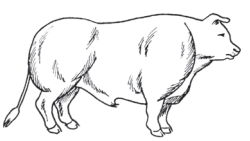

All dog breeds are **derived** from the same **genetic source** as the wolf. Over centuries, owners selectively chose dogs with specific **characteristics**, such as spots or long legs. Continuing to breed animals with particular characteristics meant that different types, or breeds, were established. This process is called **selective breeding**. It is highly controlled and leads to a small **genetic pool**. Because of the small gene pool, unwanted genetic diseases or weaknesses can occur.

☞ **1** Match the following phrases.

Selective breeding of the European	of fruit, flowers and vegetables.
Selective breeding reduces a	cabbage produced broccoli and cauliflower.
Plant breeders make new cultivars	species' gene pool.

2 Put the following characteristics and **complications** into the table.

weak hips huge heavy udders breathing difficulties
cute squashed faces big muscles for meat production can't walk comfortably
large calves and narrow birth canal graceful sloping back

	Desirable characteristics	**Complications**
Dairy cow 		
Beef cattle 		
Pug dog 		
German shepherd dog
