Evidence of a chemical change

☞ **1** Read the following descriptions of experiments that involved a chemical change. Underline the evidence of a chemical change in each experiment.

Experiment A

A test tube half full of green copper carbonate solution was heated using a Bunsen burner. The solution turned black and bubbles were produced.

Experiment B

A piece of magnesium ribbon was placed in a test tube of sulfuric acid. The liquid started to fizz and after a while the test tube felt hot to touch. When the reaction stopped, the piece of magnesium was no longer in the acid.

Experiment C

Silver nitrate solution and sodium chloride solution are both clear and colourless. When silver nitrate is poured into a test tube of sodium chloride, a white solid forms and sinks to the bottom of the test tube.

Experiment D

A spoonful of magnesium carbonate powder is mixed in a small beaker of sulfuric acid. The acid starts to bubble. When touched, the beaker feels warm.

Experiment E

The teacher drops a small piece of potassium into a beaker of water. The potassium bursts into flames and starts to move around on top of the water. It makes a sizzling sound and then the flame goes out. Soon, a horrible smell is detected. The beaker is warm to touch when the teacher pours out the water.

Experiment F

When a piece of magnesium is placed into the flame of a Bunsen burner it catches alight and emits a bright light. Once it has burnt out, all that is left is a fine grey powdery substance.
