Types of Nebulae

Nebula are clouds of gas and dust in space. There are five main types of nebulae:

* Reflection Nebulae
* Emission Nebulae
* Dark Nebulae
* Planetary Nebulae
* Supernova remnant

Type of Nebulae	Description of Nebulae	Example
Reflection Nebulae	The dust and gas of this type of nebula does not emit its own light. Instead, it reflects light from nearby stars and/or galaxies	The Iris nebulae
Emission Nebulae	These nebula make their own light. Energy from a nearby star heats up the gas and dust in the nebula. The gas and dust gets energized and starts to release light.	The Eagle nebula
Dark Nebulae	These nebula are dense and block out the light from stars and other nebula behind them.	The Horse head nebula
Planetary Nebulae	These are made when a star is dying. They have a dense central core and huge outer shell of energized gas which gives off light.	The Cats eye Nebula
Supernova remnant	When a large dying star explodes it pushes a large shock wave of energy into space. This pushes and energizes gas and dust in front of it. This gas and dust give off light.	The Crab Nebula

Question .

1. Which two types of nebula are caused by dying stars?

2. Which type of nebula has its particles energized by nearby stars?

3. Which type of nebula does not reflect or emit light, but just blocks out the light of stars behind it?

4. Where do reflection nebula get their light from?
