Rates of Chemical Reactions

Rate of Reaction is the speed at which a chemical reaction occurs.

Some chemical reactions have a slow rate of reaction. For example food rotting or iron rusting. Some chemical reactions have a fast rate of reaction. For example a hydrogen balloon exploding.

Sort the following into slow or fast chemical reactions. Put in them into the table that follows. Food rotting, gas in the Bunsen burner burning, fruit ripening on a tree, wine fermenting, wood burning, food digesting in our guts, bread rising due to yeast, a bullet cartridge exploding.

Slow rate of reaction	Fast rate of reaction

The rate of reaction can be affected by a number of things. These are:

-Temperature. E.g. food rots faster in warm weather.

-Concentration. The more concentrated an acid the quicker it will react with a metal.

-Agitation(stirring).

-Surface area of reactants

-Catalysts. Catalysts are chemicals that speed up a reaction without themselves being used up.
