Ecology

Ecology=the relations of organisms to one another and to their physical surroundings.

Survival=staying alive.

Environment=the living and non-living conditions that surround and affect a living thing.

We can divide the environment into two parts: biotic and abiotic.

Living environment=**Biotic.**

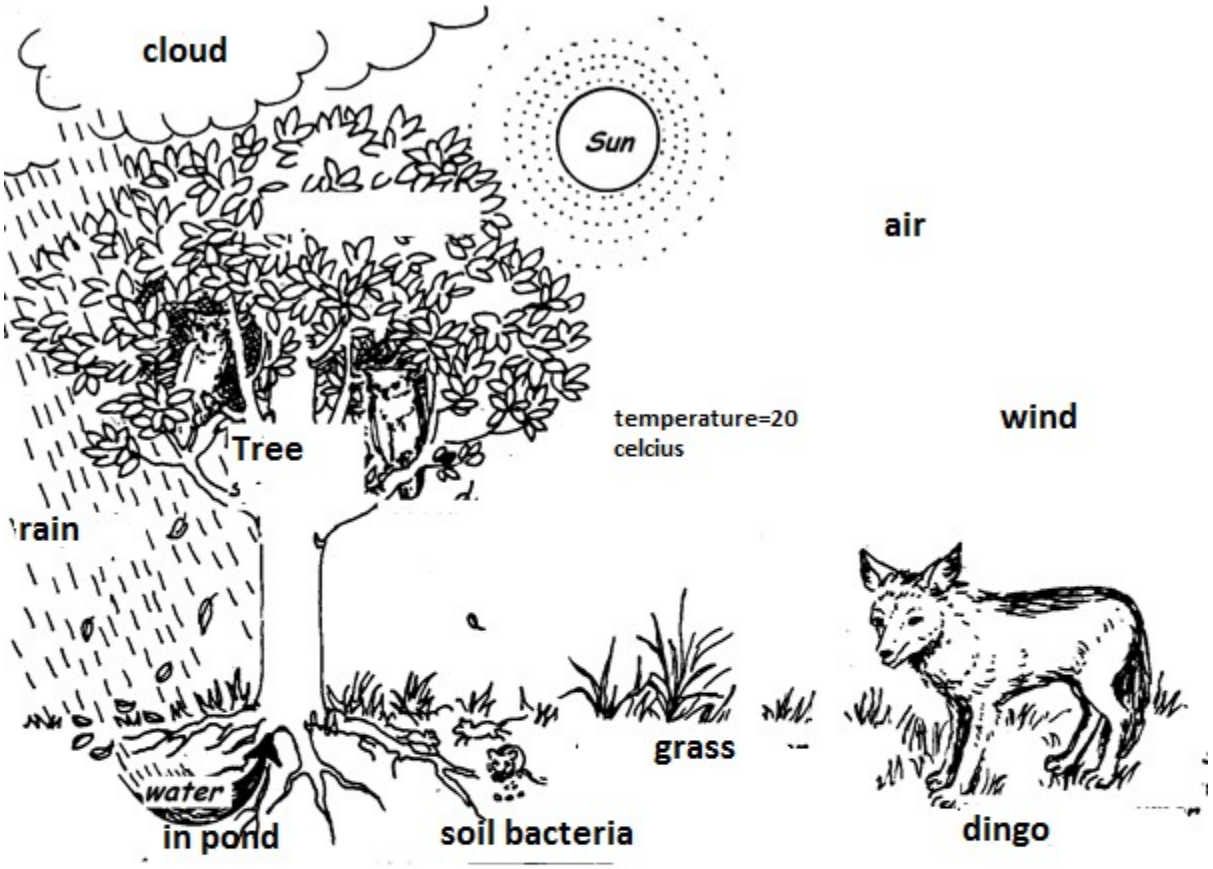

All the living things that can affect an organism's survival. For example: its food, predators, competitors, and disease causing organism.

Non-living environment=**Abiotic.**
Abiotic, meaning not alive, are non-living aspects s that affect an organisms survivals. Things like air, water, soil, sunlight, temperature, and climate.

Ecosystem=all the members of a community plus the abiotic (physical) factors influencing them.

Look at the picture on the next page. Into the table below write as many abiotic factors that you can see and as many biotic factors that you can see.

Biotic	Abiotic
