Sources of Light

We can see most objects because light bounces off of them into our eyes.

However some objects are a **source** of light as they are **luminous**. This means they produce their own light eg the sun or a torch.

Objects that do not produce their own light eg the moon or people, are **non-luminous**. They require light from another source to be seen.

Non-luminous objects can be classified into 3 groups:

Transparent – Light can travel through it easily without any interference eg glass, air, water

Translucent – Some light is transmitted but some is absorbed. Vision is interfered with eg frosted glass.

Opaque – No light is transmitted eg people, wood and metal.

When ever light is prevented from hitting a surface by an opaque object a **shadow** is formed.
