Cycles in Nature

In this topic, we need to investigate 3 important cycles: water, carbon and nitrogen.

1 In what form does carbon exist in the atmosphere?

2 Which group of organisms are responsible for 'capturing' the carbon and bringing it into the biotic world?

3 What is the name of the biological process that enables this to happen?

4 How do animals get their carbon?

5 In what form do we (animals) get our carbon?

6 What do we use this carbon for?

7 Name the three main **processes** involved in this cycle.

8 In the water cycle, there are six **processes** that take place. Name them.

9 Evaporation of water is just about equal to precipitation over the whole globe. Where is evaporation highest?

10 Where is precipitation highest?

11 Transpiration of water from leaves amounts to what percentage of the total evaporation?

12 What percentage of **all** water is fresh?

13 Where do we find the nitrogen we need?

14 Which organisms are responsible for getting this nitrogen into the biotic system?

---

15 There are 3 different types of this group of organisms. Name them.

---

16 You now need to draw a well-labelled diagram of each of these cycles.
