Evolution (p86)

Charles Darwin proposed that natural selection could result in the formation of new species. In his book *On the Origin of Species*, he called this 'modification by descent' rather than evolution. The theory of evolution states that similar species must be closely related to each other.

What is a species?

1. Define the term species. (hint: look at the glossary on page 102)

2. Describe what test was used to determine a species in the past.

3. Describe an example of an inter-breeding test.

4. How do scientists now test for species?

Speciation

1. What is speciation?

2. What is speciation responsible for?

3. What has resulted from speciation?

4. What is biodiversity?

The process of speciation occurs in three basic steps. Describe each step in the space below.

Step 1: Variation

Step 2: Isolation

Step 3: Selection
