Interphase	
Prophase	
Metaphase	
Anaphase	
Telophase	
Interphase	

▪ The cell functions as normal ▪ The DNA is in the form of threadlike chromatin ▪ The DNA duplicates itself
▪ New nuclear membranes start to form around the chromosomes ▪ The cell pinches in the middle and splits into two ▪ The chromosomes start to unwind
▪ The DNA unwinds into threadlike chromatin ▪ The two new cells function normally
▪ The DNA condenses into visible chromosomes ▪ Each chromosome now has an identical copy attached at a centromere ▪ The nucleus membrane breaks down ▪ The spindle begins to form around the chromosomes
▪ The chromosomes line up in the centre of the cell ▪ A spindle fibre attaches to the centromere of each chromosome
▪ The chromosomes separate at the

centromere

- The spindle fibres contract, pulling half of each chromosome to each end of the cell
