Where Did the Universe Come From?

Steady State Model. This is the old explanation. This says that the universe is infinite in size and has always existed the way it is today.

Infinite means never ending.

Big Bang Theory. This is a newer idea. It states that at one time in the past all of the matter in the universe was in one place. It then exploded (Big Bang) and all the matter started to spread out forming the universe.

A man called Hubble worked out the Big Bang Theory. By studying light he noticed that the Galaxies in the universe were spreading out. He thought if they are all spreading out they must have all started in one place.

Distance in Space

In space because the distances are so far apart we have to use special units of measure.

Light year. This is the distance light travels in one year. It is equal to 9.5 trillion km (9500000000000km).

Try these

Light Years (ly)	To go from light year to Km multiply by 9500000000000. To go from Km to light years divide by 9500000000000	Km
1		9500000000000
2		
		28500000000000
0.05		

Parsec. This is an even bigger unit of measure for distance. One parsec is close to 3 light years. Sometimes Mega parsecs are used.
