How Organisms Affect Each Other

The names, descriptions and examples of organisms affecting each other are mixed up.

Cut out each of the boxes below and glue them in the correct order in your notes.

Name	Description	example
Competition	A relationship where only one organisms benefits and the other is neither benefited or harmed.	Snails eat the green leaves of plants.
Predation	Two organisms live closely together but only one benefits from the relationship. The other suffers but does not often die. It is not in the parasites interests for the host, its food source, to die.	Clown fish (Nemo) live amongst the stinging cells of the sea anemone. They eat the anemone's left over food and are protected by the stinging cells from predators. The sea anemone are not harmed by the Clown Fish nor do they benefit from their presence.
Mutualism	Organisms compete for the same resources, eg: space, food, water nesting sites.	The WA Christmas tree gains water in a dry environment by tapping into the roots of other trees.
Parasitism	One organism eats either whole or part of another for food	Bees feed on the nectar found in flowers. While they are feeding some pollen collects on their bodies. When they visit the next flower they pollinate the flower.
Commensalism	Two organisms live closely together and *both* benefit from the relationship.	There is one pond containing beetles which both frogs and green snakes require as a food source.
